Interferometric GW Detectors

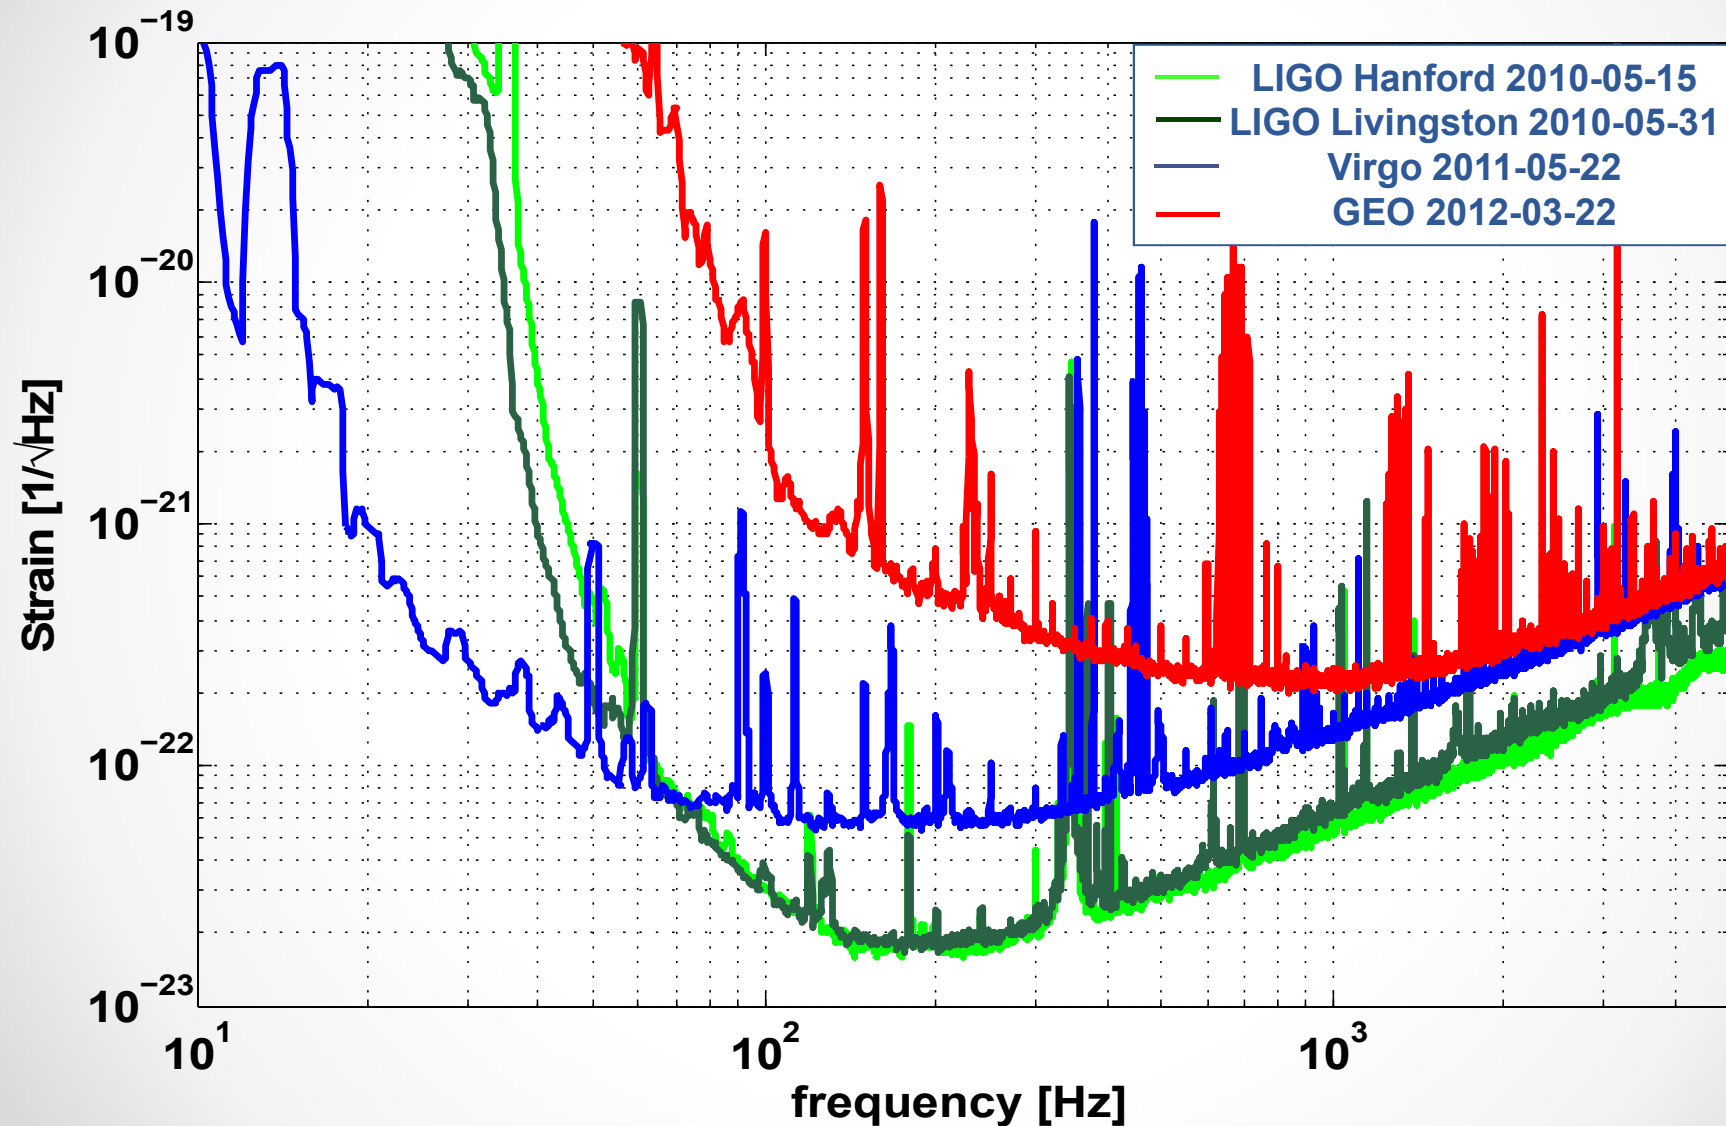

$$h = \frac{2\Delta L}{L}$$

Amplitude h on Earth:

- $h \sim 10^{-21}$ (GW150914)
- $L = 1\text{m}$, $\Delta L = 10^{-21}\text{ m}$
- $L = 3\text{km}$, $\Delta L = 10^{-18}\text{ m}$

Final Sensitivities of the First Generation

Commissioning progress of (Advanced) Virgo

The first generation

- The first generation detectors were constructed between the mid 90s and 2000s; they reached the design sensitivity; observations for some years
- Sensitivity sufficient to reach 200 galaxies, but...
- Compact-object mergers occur only once per 10.000 years per galaxy...
- Necessary to reach more galaxies

The second generation

- During observations with the first generation, more advanced technologies were developed for the second generation
- Advanced detectors will be about 10x more sensitive, reach of order 100,000 galaxies
- Accordingly, one should see several tens of signals per year

Global Network of Detectors

The Birth of Virgo

Virgo was conceived in
the 80s

Construction completed in July 2003

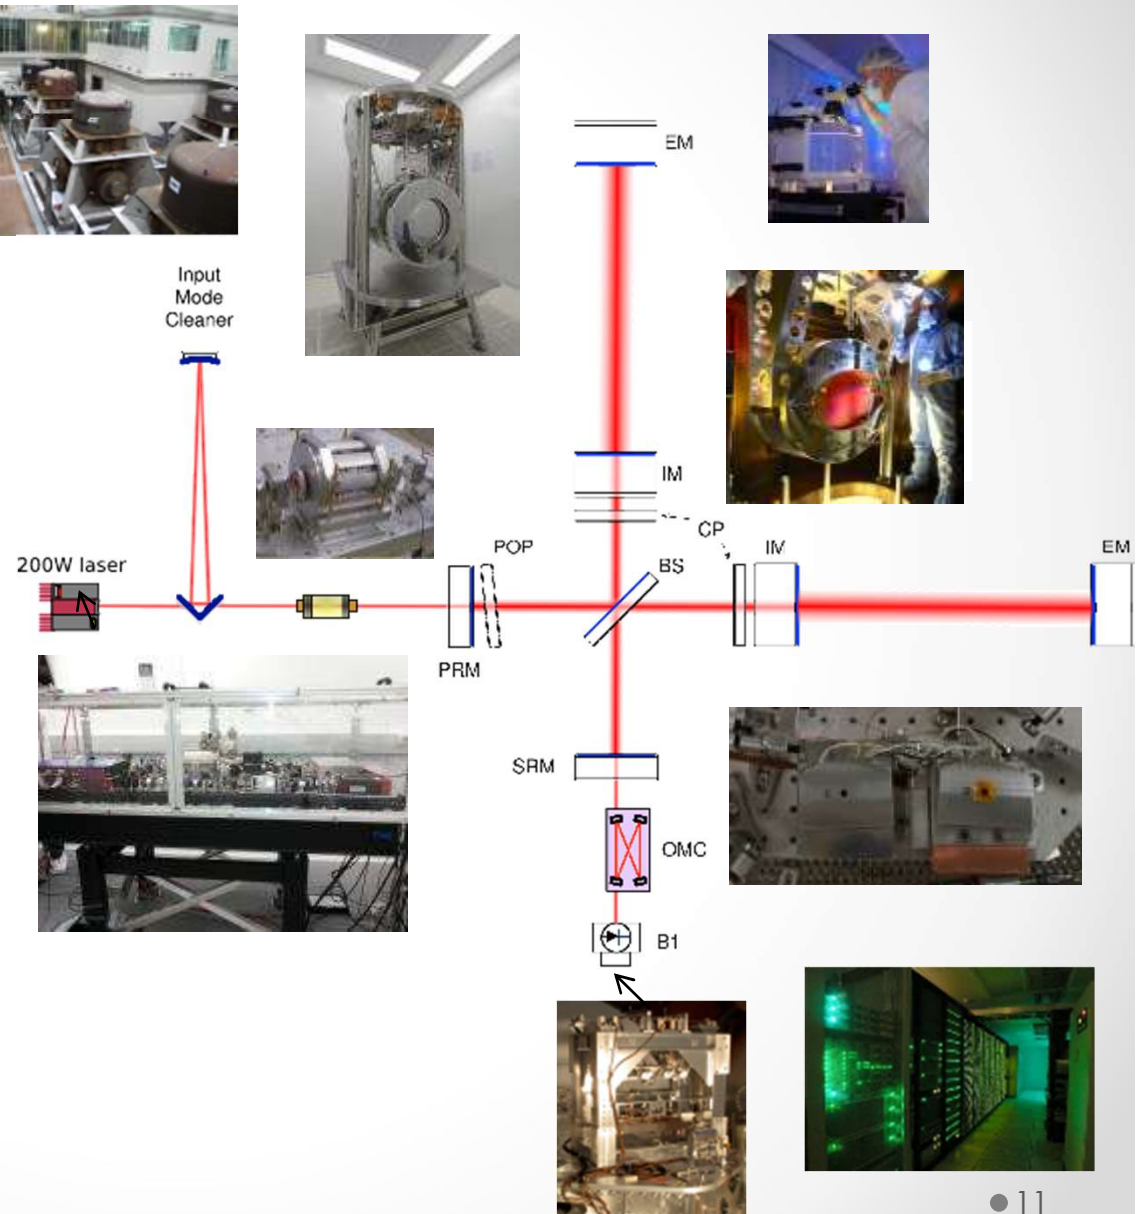

Founding fathers of Virgo:
Alain Brillet and Adalberto Giazotto

Summary: Advanced Virgo

What's Advanced?

Parameter	Initial Virgo	Advanced Virgo
Laser power	20 W, input 20 kW, arm	125 W, input 700 kW, arm
Test mass	20 kg	42 kg
Interferometer topology	Power-recycled Fabry-Perot Michelson with arm cavities	Dual-recycled Fabry-Perot Michelson with arm cavities
GW Readout Method	RF heterodyne	DC homodyne
Best sensitivity	5×10^{-23} / rHz	Tunable, better than 5×10^{-24} / rHz in wide band

Virgo Infrastructure: 3km Vacuum Tube

Light travels in ultra-high vacuum.

Only few molecules crossing the laser beam cause an observable change in path length masking GWs

Cover the tube:
stop roaming cars and
projectiles of hunters

Dangers at LIGO

Vacuum Chambers

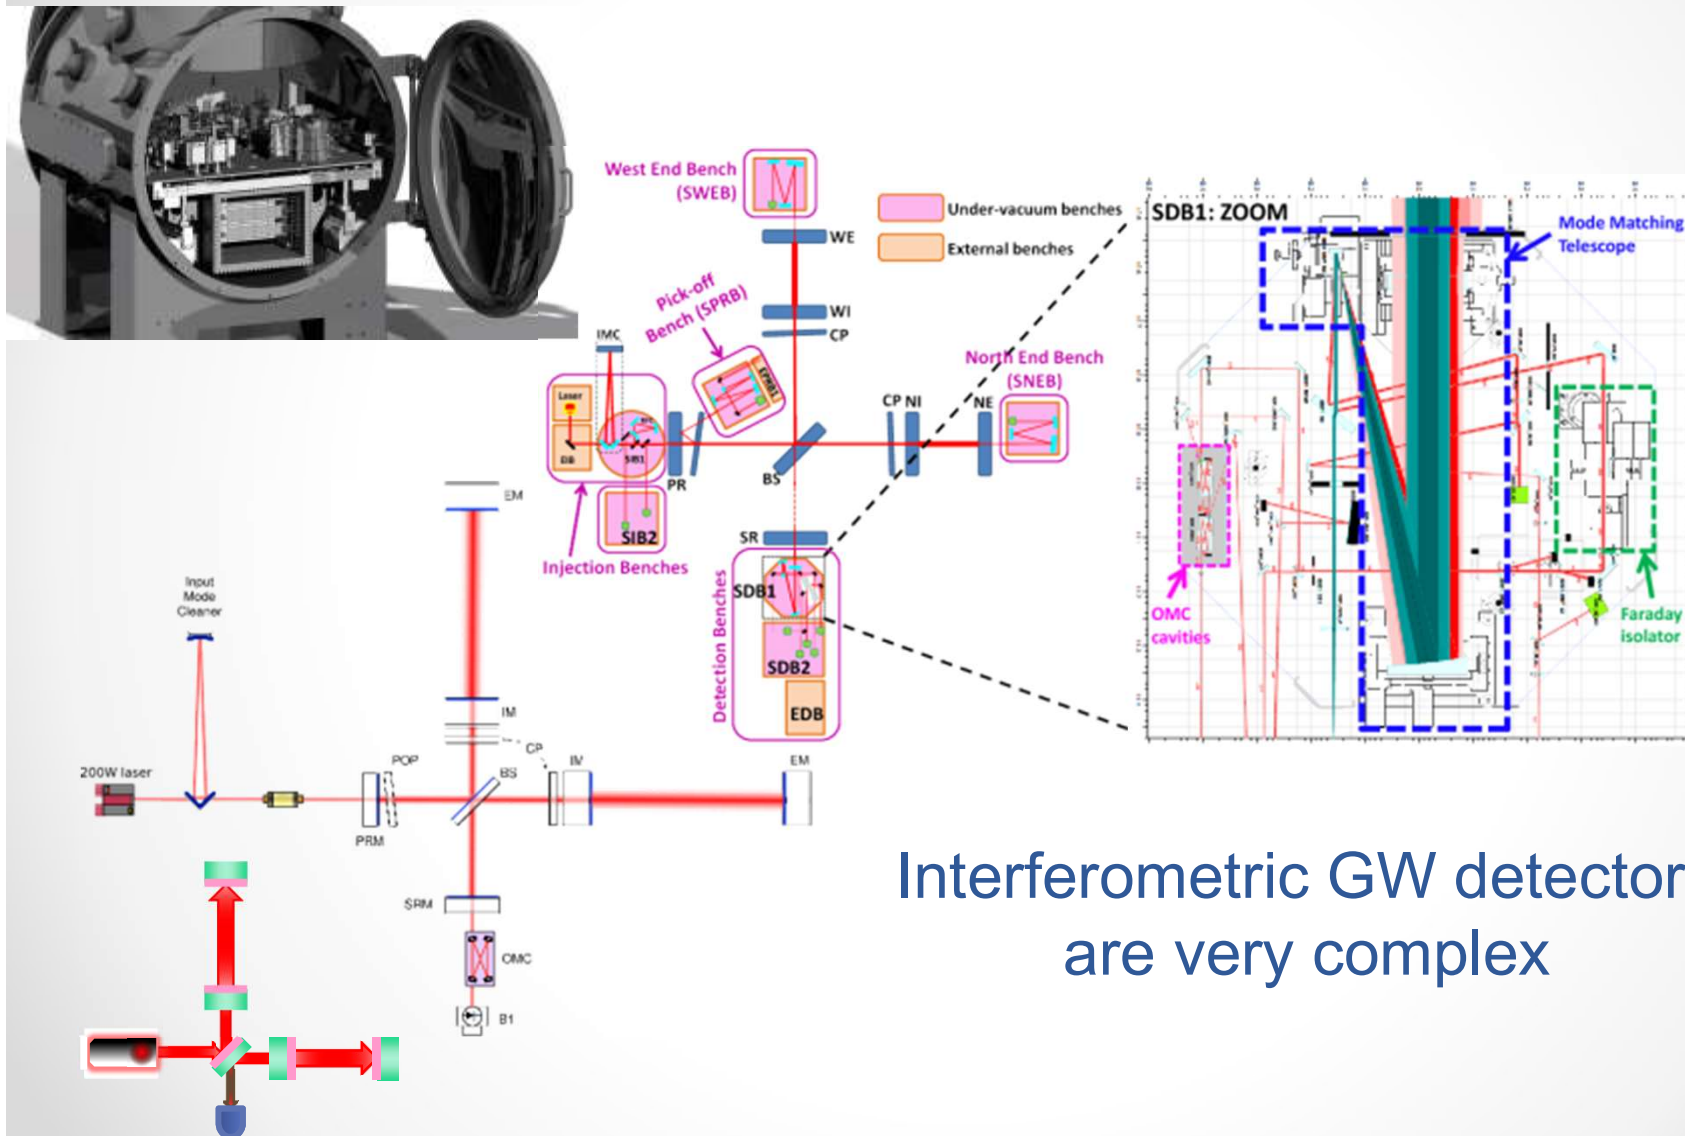

Central building

Work inside the chamber

Levels of Representation

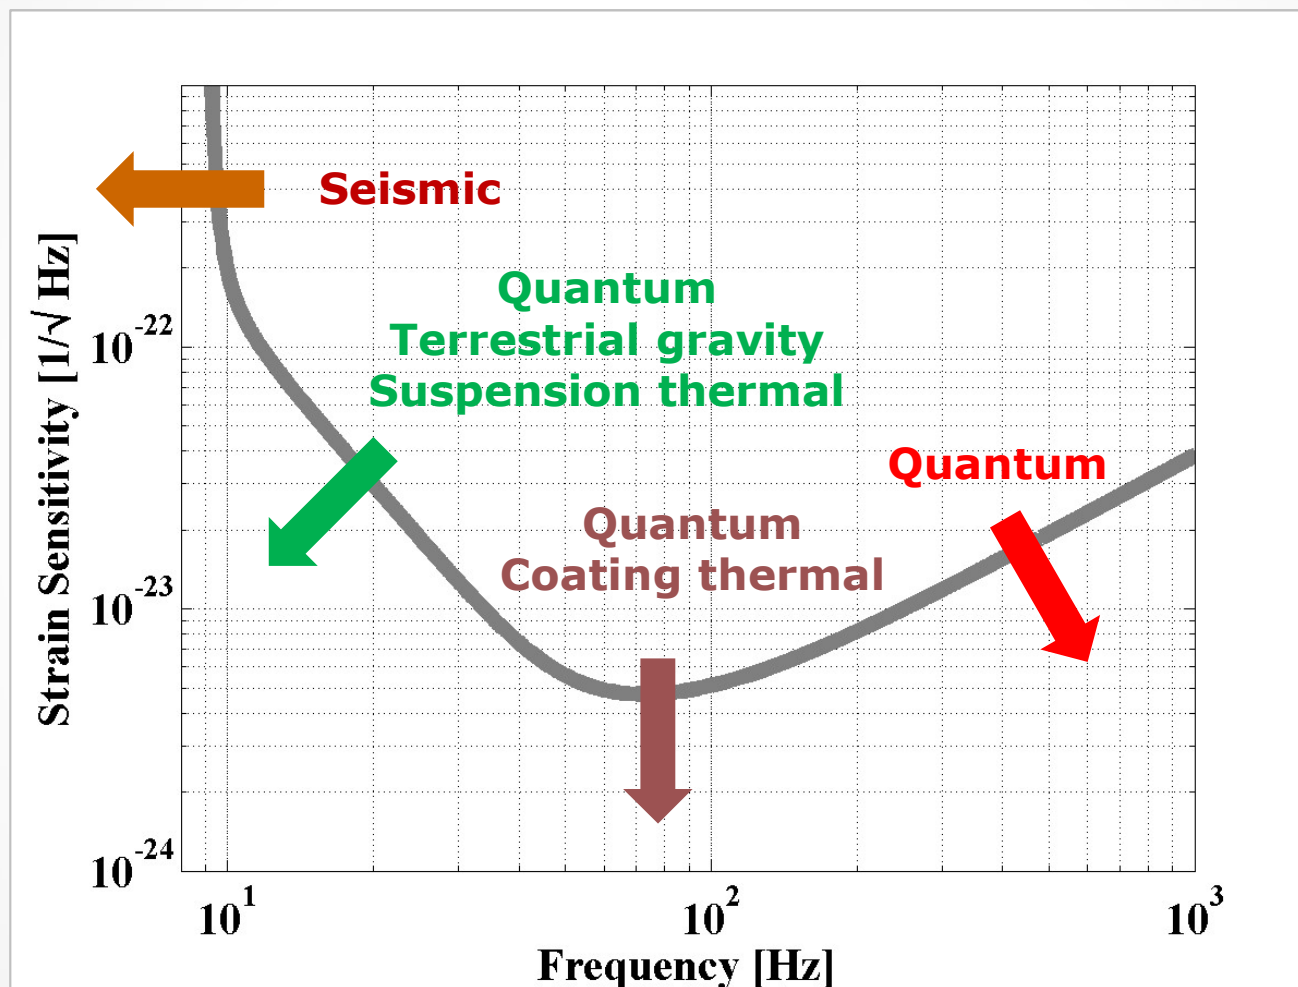

Interferometric GW detectors
are very complex

Virgo Configuration

Main Noise Sources

Adv Virgo Noise Budget

Principles of Seismic Isolation

Damping

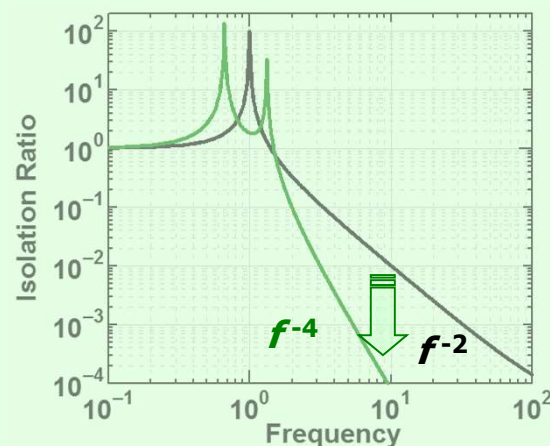

Lower peak height

Less isolation

Cascaded

Steeper isolation curve

More peaks

Larger structure

Lower resonance frequency

Difficult to realize

In practice: use combination of these methods

Seismic Isolation of Adv Virgo

Mechanical filters

Passive isolation

Superattenuator

Suspension System of Adv Virgo

Test mass

Beam splitter

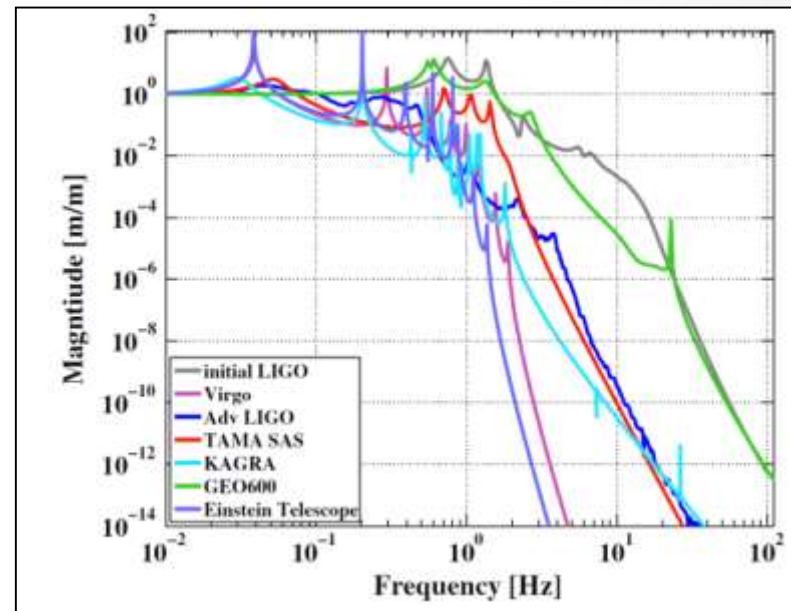

Seismic Noise

Ground motion at the Virgo site

Modelled seismic isolation performance

Quantum Noise

Heisenberg uncertainty
principle

$$\Delta p \Delta x \geq \frac{\hbar}{2}$$

Caves: it is the state of the field incident from the output that determines the photon statistics

Fundamental
measurement in Virgo:
Counting photons

What are the position and momentum variables in the case of light?

Multiple answers, but for GW detectors, the conjugate variables are the **quadratures of the EM field**:

$$E(t) = E_1(t)\cos(\omega_0 t) + E_2(t)\sin(\omega_0 t)$$

High-Power Laser

- Stabilized in power and frequency
- Master-slave configuration

A new laser is being developed.

Squeezed-Light Technology

Squeezed light is produced by parametric down-conversion in non-linear crystals

Squeezing Ellipses

Test Mass

- Requires advanced technologies for substrates and polishing
- Coating deposition pushes current technology limits
- Sub-nm profile errors over 30cm

Designed to

- Have ultra low mechanical loss and high resonance frequencies (vibration)
- Have extremely low absorption, low scattering, high homogeneity, precise curvature and profile

Thermal Noise

Substrate thermal noise

- **Thermo-elastic noise**
- Brownian noise

Coating thermal noise

- **Brownian noise**
- Thermo-refractive noise
- Thermo-elastic noise
- Photothermal noise

Suspension thermal noise

- Brownian noise
- **Thermo-elastic noise**

Dissipation and Thermal Noise

Thermo-elastic noise:
Irreversible heat flux across
temperature gradients

Brownian noise:
Many possible causes
(for example, change in
silicon bonds)

Fluctuation-dissipation theorem:
Thermal-noise spectrum proportional
to mechanically dissipated power

$$S_x(\Omega) = \frac{8\pi kT}{\Omega^2} \frac{W_{\text{diss}}}{F_p^2}$$

Zheng et al 2010

Newtonian Gravitational Noise

Seismic noise

$$\frac{\xi(f) e^{-\frac{2\pi f h}{c_{\text{hor}}}}}{f^2}$$

Advection temperature
fluctuations

$$\frac{\delta T(f) e^{-\frac{2\pi f r}{v}}}{f^{10/3}}$$

Infrasound

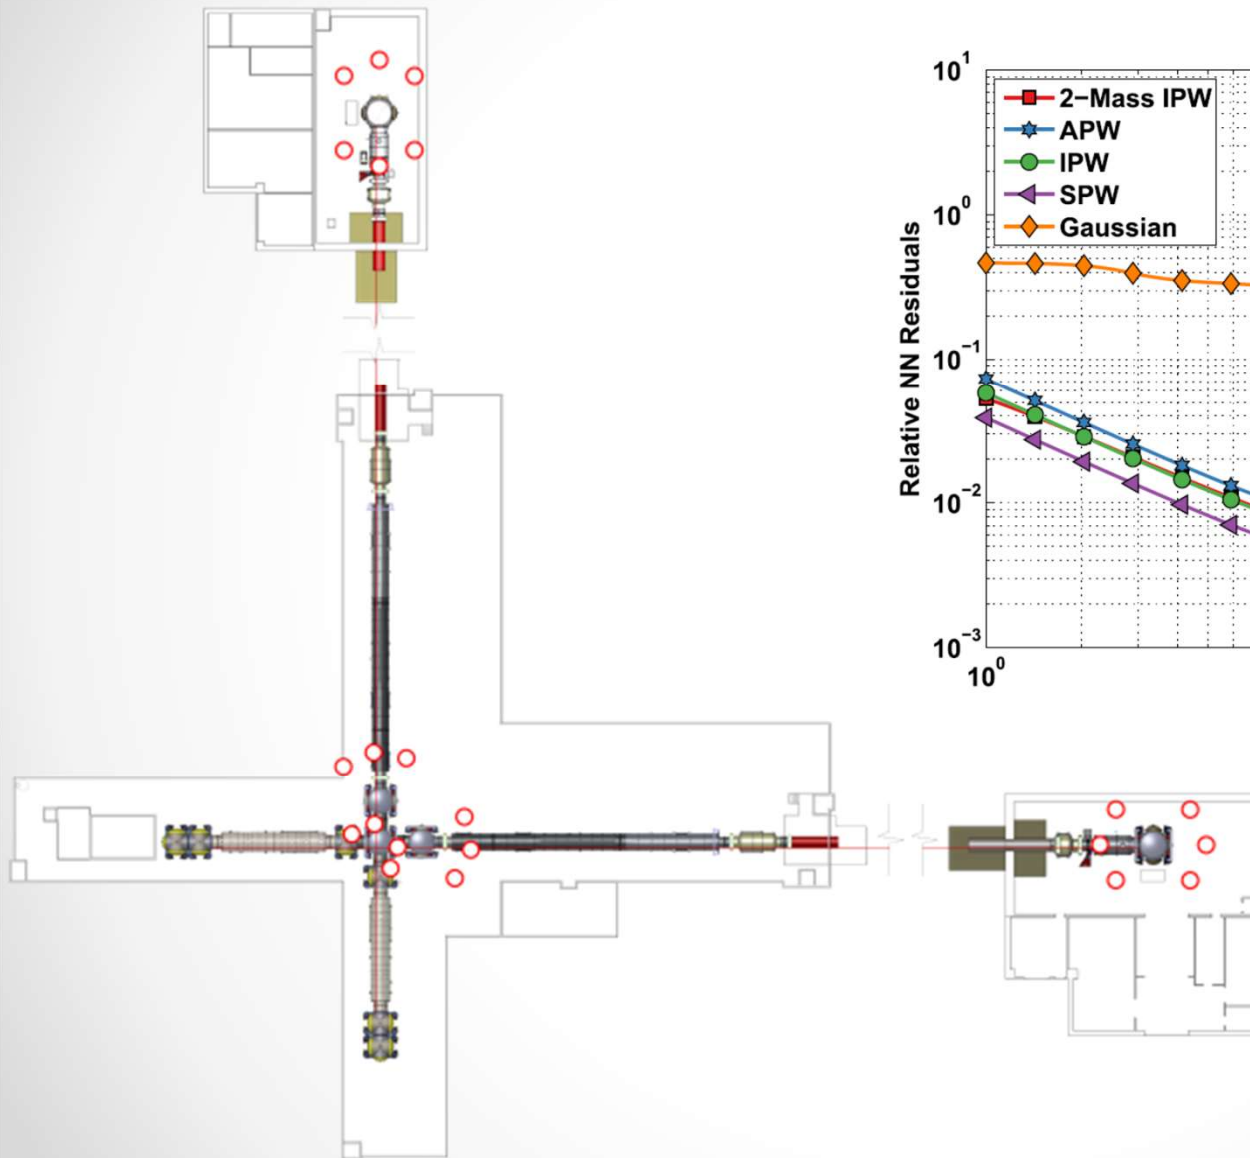

$$\frac{p(f) e^{-\frac{2\pi d f}{c_{\text{hor}}}}}{f^3}$$

Newtonian Noise in LIGO

- Seismic surface waves
- Vibrations of buildings
- Vibration of water tubes
- Vibration of vacuum system
- Ventilation fan
- Sound inside and outside laboratory building

Newtonian-Noise Cancellation

Future Key Technologies

- Quantum-noise reduction by squeezing and QND
- Interferometer control to address non-linear couplings and non-stationary noise
- Adaptive optics to reduce optical loss
- Coating thermal-noise reduction
- Cryogenics for mirror and suspension cooling
- Suppressing parametric instabilities due to high laser power
- Coherent cancellation of environmental noise

Einstein Telescope

Triangular xylophone

Constructed a few 100m underground

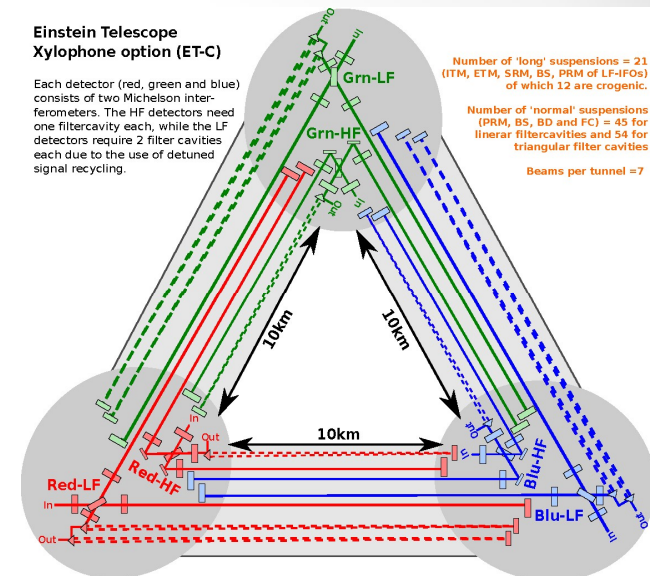

Einstein Telescope
Xylophone option (ET-C)

Each detector (red, green and blue) consists of two Michelson interferometers. The HF detectors need one filtercavity each, while the LF detectors require 2 filter cavities each due to the use of detuned signal recycling.

Number of 'long' suspensions = 21 (ITH, ETH, SRM, BS, PRM of LF-IFOs) of which 12 are crogenic.

Number of 'normal' suspensions (PRM, BS, BD and FC) = 45 for linear filtercavities and 54 for triangular filter cavities

Beams per tunnel = 7

ET parameters

10km arm length

200kg mirrors

3MW light power (high tone)

10K substrates (low tone)

ET Sensitivity

Future Scenario I

A Facilities of advanced detectors

B 3rd generation

LISA

Bonus: synergy

Future Scenario II

C

SOGRO

MIGA

Torsion bar

D

Liquid He

Ultimate Decigo / Big Bang Observer

E

Earth/Moon
